Answer each of these in 2-4 sentences.

1. Describe your weekly study process. What has been effective in the past? Is there anything you're planning to update?
    a. Starting a little early has never harmed anyone, so this semester, for CS156 especially, I've been starting PCW the night before, and finished it around 3 hours before class.
    b. In CS concentrations specifically, I have had a track record of using AI to cover more of the advanced coding parts for me, which is a habit I aim to get rid of this semester, by prioritizing learning the nitty gritty coding parts, trying hard to code and only using AI in a teaching fashion, reading over ever line it writes and having it explain the parts I don't understand myself to me.
    c. Moreover, I am a sucker for handwritten notes (they don't have to be organized, just written down) and have been carrying around a notebook to note down points, equations, questions and answers while doing the PCW and even during class.
    d. In these upcoming weeks, I book a block of time on Saturday to work on the upcoming pipeline assignments, to learn incrementally and implement what I learned that week as I go along, rather than all together, all at once.

2. Which course objective is most worrying to you? Who is a classmate you think exemplifies this skill?

a. ***#CS156-MLCode*** is most worrying to me for the aforementioned reasons (having not enough practice with Python beyond basic functions and a bout of game development when I was 12), so delving into Machine Learning with Python seems scary to me, but necessary.
b. I think ***Hectar*** exemplifies this skill very well, as a close friend of mine I know that he is really good at coding as well as adapting new skills to old ones, so I don't doubt that he will make that machine **LEARN.**

3. For each HC you tagged above, describe how it is related to the class.
    a. ***#algorithms:*** is a bit of an obvious one, but if I haven't stated it enough in this coversheet, I am extremely unconfident of my programming skills, and believe that this class is possibly my last Minervan chance to improve them. This means coding the hard parts by myself, not relying on LLMs for anything except support, and putting in the maximum effort to produce not only something that works, but something that I am proud of, and put on this very portfolio.
    b. ***#complexcausality:*** I am excited to examine the interconnectedness (or lackthereof) of parameters to the outcomes, and vice versa. It will be interesting to find connections between features I never thought there would be, and develop a sixth sense for networks as the machine does the same.
    c. ***#persuasion:*** this might be a weird one to include here, but as prof. Watson said in class and in the capstone kickoff, researchers are on the constant lookout for things that make the smallest of difference, which is a feat in and of itself. However, to make any actual impact external to this class, I need to be able to convince others that this tiny correlation, this model that predicts when I need to run the washing machine, this thing that does something that nobody thought they ever needed, is important.
